Annual Recommendations (please check all items you'd like to discuss during your visit with us):

- DHPP Vaccination.** After the initial vaccine series is completed, it is recommended to repeat the "Distemper Combo" vaccine every 3 years to protect against several viral agents important for the health of your pet (Canine Distemper, Adenovirus/Hepatitis, Leptospirosis, Parainfluenza, Parvovirus. This vaccination is extremely important for pets and can help to prevent the diseases just by vaccinating.
- Rabies Vaccination.** Rabies is always fatal (animals and humans) when contracted! Since there is no cure, prevention by vaccination is the only solution. Vaccination is extremely important AND required by law, as humans can transmit Rabies easily. After the initial vaccination is completed, it is recommended to repeat the Rabies vaccine every 3 years.
- Bordetella Vaccination.** This yearly vaccine protects against the upper respiratory disease that is best described as an infectious bronchitis. While it usually is not fatal it can cause great discomfort for dogs and can be extremely annoying to the owner. It is recommended to complete the Bordetella vaccination every 6 months if going to public places often (boarding, grooming, dog parks/beaches, etc).
- Leptospirosis Vaccination (lifestyle vaccine).** After the initial vaccine series is completed, it is recommended to repeat the vaccine yearly to protect against the Leptospirosis disease. Dogs can be infected by leptospirosis when abraded skin comes into contact with infected urine or with water contaminated with infected urine. It can also be spread by bite wounds, reproductive secretions, and even consumption of infected tissues can transmit this infection. If infected, the disease can be transmitted from dogs to humans.
- Lyme Vaccination (lifestyle vaccine).** Dogs that are involved in outdoor sports, camping, hunting or hiking in wooded areas should be vaccinated for Lyme disease. Lyme disease is a serious, debilitating disease that is spread by the bites of the common deer tick. After the initial vaccine series is completed, it is recommended to repeat the Lyme Vaccination yearly.
- Rattlesnake Vaccination (lifestyle vaccine).** A "snake-bite vaccine" may be useful if you live in an area, or visit areas, that have sightings of venomous snakes. Anecdotal evidence suggests that the Rattlesnake vaccine may lessen the severity of signs from a snake-bite but does not act as a "cure." Pets that have been bitten by a venomous snake should still be taken into your Veterinary hospital or a Veterinary Emergency Clinic immediately for further care and observation even if the pet has been vaccinated with the Rattlesnake vaccine. After the initial vaccine series is completed, it is recommended to repeat the Rattlesnake Vaccination yearly.
- Heartworm Test.** Heartworm is a fatal disease spread only by the bite of mosquitoes. It is not super prevalent here but is a 100% preventable and many of the monthly heartworm preventatives will also deworm the pet once a month as an added benefit. The test is highly recommended whether or not your pet is an inside or outside pet, as well as whether or not your pet is on heartworm preventatives year round. Since it only takes one mosquito bite to cause disease, all pets are vulnerable. The test requires a small blood sample and can be preformed while you wait.
- Intestinal Parasite Screen.** Since some internal parasites can infect people, yearly stool tests protect both your pet and your family. There are 12 common intestinal parasites that you pet may be exposed to on a regular basis. Dogs put all sort of things in their mouths. Therefore, it is important to check annually for parasites. The test is performed by examining a small quantity of stool through a microscopic flotation exam to identify characteristic parasite eggs.
